A computer interface device has a housing configured with a first sensor for detecting a position change of the computer interface device on a surface, a touch pad configured with the housing for generating touchpad signals, and a wireless link to transmit the first pair of parameters and the touchpad signals to a computing device. In an application, the first sensor provides a first pair of parameters to indicate the position of the housing on the surface and control cursor displayed on a screen of the computing device. The touch pad may be configured to detect gestures and provides signals responsive to the gestures over a wireless link for controlling a displayed object or attribute on the screen of the computing device. The touch pad may also be configured to detect a plurality of contacting fingers and to provide signals over a wireless link used to control a displayed object or attribute on the screen of the computing device.

CROSS REFERENCE TO RELATED
APPLICATIONS

[0001] This application is a continuation of U.S. application Ser. No. 10/779,368, filed on Feb. 13, 2004.

BACKGROUND OF THE INVENTION

[0002] 1. Field of the Invention

[0003] This invention relates to user interface devices for use with a computer, and in particular to computer mice, trackballs, touchpads, multiple-parameter pointing and data entry devices, and user interface metaphors.

[0004] 2. Description of the Related Art

[0005] User interface devices for data entry and graphical user interface pointing have been known for many years. The most common devices include the computer mouse (usually attributed to English, Engelbart, and Bennis "Display-Selection Techniques for Text Manipulation, IEEE Transactions on Human Factors in Electronics, pp. 5-15, vol. HFE-8, No. 1, March 1967), the trackball, the touchpad in both finger-operated (for example, the various finger-operated devices produced by Symantec Corp., of Springfield, Oreg.) and stylus-operated (for example, products used with desktop workstation computers—Wacom Technology Corp., of Vancouver, Wash.) versions, and display-overlay touchscreens. Other historical and exotic devices include various types of light pens and the Data love™ (produced by VPL Research, Inc., of Redwood City, Calif.).

[0006] Most user interface devices for data entry and graphical user interface pointing commonly used with computers or with equipment providing computer-like user interfaces have two wide-range parameter adjustment capabilities that are usually assigned to the task of positioning a screen cursor within a two-dimensional display. In many cases, one, two, or three binary-valued "discrete-event" controls are provided, typically in the form of spring-loaded push-buttons.

[0007] More recently, computer mice have emerged that provide an additional "scroll" finger-wheel adjustment (for example, between two control buttons) to provide a third wide-range parameter adjustment capability (for example, various products developed by Logitech Inc., of Fremont, Calif.). A mouse of this configuration is often referred to as a "Scroll Mouse" since this third wide-range parameter is typically assigned the task of positioning a vertical scroll bar in an actively selected window. This additional finger-wheel adjustment may also operate as a spring-loaded push-button, thus providing an additional binary-valued "discrete-event" control. Typically this additional binary-valued "discrete-event" control is used to turn on and off an automatic scrolling feature which controls the rate and direction of automatic scrolling according to vertical displacement of the displayed cursor.

SUMMARY OF THE INVENTION

[0008] In accordance with embodiments of the invention, two independently adjustable and positionable cursors are employed in a visual interface for editing an electronic document. The document may comprise text symbols, text objects, and graphics objects, among others. If both cursors are located in close proximity within the document, then these

cursors may be simultaneously displayed in a single window. Otherwise, two areas of the document, each comprising one of the cursors, may be simultaneously displayed using a separate window for each cursor, or alternately selected and displayed in a single window. Copy or cut operations may be made with one cursor, while paste operations may be repeated using the second cursor. Cursor locations may be left unchanged, or they may be moved between or within editing operations. The two cursors may be freely controlled by an enhanced pointing device, such as a mouse with an added touchpad or trackball, or sequentially selected and controlled by a conventional mouse.

[0009] In accordance with embodiments of the invention, a traditional hand-movable computer mouse is configured with an additional user interface sensor. For convenience, the term "user interface sensor" will be used herein to collectively refer to devices such as trackballs, touchpads, mouse devices, scroll-wheels, joysticks, and other such devices.

[0010] In one aspect of the invention, the addition of a user interface sensor provides alternative physical modalities for the same pair of adjustable parameters so that a user may switch between using the user interface device as a traditional hand-movable computer mouse and using the user interface device as a trackball or touchpad.

[0011] In another aspect of the invention, the addition of a user interface sensor provides alternative resolution modalities for the same pair of adjustable parameters so that a user may switch between using the invention as a traditional hand-movable computer mouse to obtain one level of parameter adjustment resolution, and using the invention as a trackball or touchpad, for example, to obtain a different level of parameter adjustment resolution.

[0012] In another aspect of the invention, the addition of a user interface sensor provides alternative types of warping modalities for the same pair of adjustable parameters so that a user may switch between using the invention as a traditional hand-movable computer mouse to obtain one type of parameter adjustment (for example, linear) and using the invention as a trackball or touchpad, for example, to obtain a different type of parameter adjustment (for example, logarithmic, gamma-corrected, arccosine, exponential, etc.).

[0013] In another aspect of the invention, the addition of a user interface sensor provides alternative offset modalities for the same pair of adjustable parameters so that a user may switch between using the invention as a traditional hand-movable computer mouse to obtain one type of centering of parameter adjustment and using the invention as a trackball or touchpad, for example, to obtain a different centering of parameter adjustment.

[0014] In another aspect of the invention, the addition of a user interface sensor may be used to provide additional parameters that may be simultaneously controlled.

[0015] In another aspect of the invention, the addition of a user interface sensor may be used to provide additional parameters that are of a different isolated context from those assigned to a traditional hand-movable computer mouse.

[0016] In a further more detailed aspect of the invention, the addition of a touchpad may be used to provide many additional parameters that are of a different context than those of a traditional hand-movable computer mouse.

[0017] In a further more detailed aspect of the invention, the touchpad may be a null-contact touchpad adapted to measure at least one maximum spatial span of contact in a given direction.

[0018] In a yet further detailed aspect of the invention, the null-contact touchpad is adapted to measure at least one maximum spatial span of contact in a given direction at a specifiable angle.

[0019] In an additional further detailed aspect of the invention, the null-contact touchpad is adapted to measure pressure applied to the null-contact touchpad.

[0020] In a further more detailed aspect of the invention, the touchpad may comprise a pressure sensor array touchpad adapted to measure, among other things, one or more of the following: the rocking position of a contacting finger in a given direction; the rotational position of a contacting finger; the pressure of a contacting finger; and parameters relating to a plurality of contacting fingers.

[0021] In another aspect of the invention the addition of a user interface sensor may be realized via a replaceable module accepted by an adaptation of a traditional hand-movable computer mouse. In this implementation, a user may initially obtain the invention in one configuration and field-modify it to another configuration.

[0022] In another aspect of the invention, a traditional hand-movable computer mouse may be implemented as a removable module in a laptop computer or other affiliated equipment, and may include a wireless link with the laptop computer or other affiliated equipment.

[0023] In yet a further aspect of the invention, a traditional hand-movable computer mouse is implemented as a removable module in a laptop computer or other affiliated equipment, and the mouse further comprises a user interface sensor.

[0024] In another aspect of the invention, a traditional hand-movable computer mouse additionally comprises a trackball or touchpad, for example. In this aspect, the mouse comprises a wireless link to an associated computer or other affiliated equipment.

[0025] In another aspect of the invention, a visual display is provided.

[0026] In another aspect of the invention, an auditory output is provided.

[0027] In another aspect of the invention, two or more individual user interface sensors may be combined without incorporation of such sensors with a traditional hand-movable computer mouse.

BRIEF DESCRIPTION OF THE DRAWINGS

[0028] The above and other aspects, features and advantages of the present invention will become more apparent upon consideration of the following description of preferred embodiments taken in conjunction with the accompanying drawing figures, wherein:

[0029] FIGS. 1a-1i illustrate various exemplary implementations involving merging, selecting, multiplexing, and pre-processing distributed in various ways between the body of the user interface device and an associated piece of equipment;

[0030] FIGS. 2a-2c depict an embodiment of the invention comprising a traditional mouse fitted with a trackball, illustrating three exemplary button configurations;

[0031] FIGS. 3a-3c depict an embodiment of the invention comprising a traditional mouse fitted with a touchpad, illustrating three exemplary button configurations;

[0032] FIGS. 4a-4d depict various exemplary degrees of freedom that may be measurably assigned to a trackball for interactively controlling parameters in a user interface;

[0033] FIGS. 5a-5d depict various exemplary degrees of freedom that may be measurably assigned to a touchpad for interactively controlling parameters in a user interface;

[0034] FIG. 6 depicts an exemplary implementation of the invention directed towards the control of both a traditional text cursor and a dual-scrollbar in a typesetting application;

[0035] FIG. 7 depicts an exemplary implementation of the invention directed towards the active selection from a clip-art or symbol library and adjustment of positioning or other attributes of the active selection in a drawing or layout application;

[0036] FIG. 8 is a flowchart showing exemplary operations and overhead involved in selecting and adjusting a specific pair of parameters from among a larger group of adjustable parameters;

[0037] FIGS. 9a-9b illustrate how the exemplary operations and overhead depicted in FIG. 8 introduce excessive overhead in situations where many parameters with a larger group of adjustable parameters must be adjusted in pairs;

[0038] FIGS. 10a-10b illustrate one technique for adding an additional scroll-wheel to a conventional scroll-wheel mouse;

[0039] FIGS. 11a-11b illustrate a simple example of open adjustments being made within various levels of hierarchy of graphical object groupings;

[0040] FIG. 12 illustrates aspects of the 3D orientation of an object in 3-dimensional space, and in particular the three coordinates of position and the three angles of rotation;

[0041] FIGS. 13a-13b illustrate one technique for using two cursors in a text cut-and-paste operation; and

[0042] FIGS. 14a-14d illustrate exemplary embodiments of a mouse where the traditional mouse buttons have been replaced by trackballs or touchpads.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0043] In the following description, reference is made to the accompanying drawing figures which form a part hereof, and which show by way of illustration specific embodiments of the invention. It is to be understood by those of ordinary skill in this technological field that other embodiments may be utilized, and structural, electrical, as well as procedural changes may be made without departing from the scope of the present invention.

[0044] By way of overview, a number of different applications that take advantage of the functionality of additional, wide-range adjustment parameters will now be discussed. In one example, an additional finger-wheel adjustment device providing a third, wide-range parameter adjustment capability is typically assigned to vertical scroll bar positioning. In accordance with the invention, such a design may be supplemented with a fourth, wide-range parameter adjustment capability so that a horizontal scroll bar position control may be achieved. With the increasing popularity of the web (with many web pages wide enough to require horizontal scrolling) and publisher layout tools (typically involving pages wide enough to require horizontal scrolling), as well as the need for simultaneous interactive horizontal and vertical scrolling actions that do not disturb a screen cursor location when using "zoom" controls, a fourth wide-range parameter adjustment capability in traditional user interface devices for data entry and graphical user interface pointing is quite valuable.

[0045] There are many other potential uses for additional wide-range adjustment parameters in traditional user inter-

face devices for data entry and graphical user interface pointing. Some opportunities have wide-range applicability, such as in providing interactive separate adjustment of the selections for “cut” or “copy” operations from the interactive adjustment of insertion location or selection for a “paste” operation. Other opportunities are more specialized but still widely applicable, such as making an active selection from a clip-art or symbol library and adjusting the position or other attributes of said active selection in a drawing or layout application. Yet other opportunities may be very specialized, such as in 3D modeling, data visualization, advanced color adjustment, lighting control, machine control, or audio and image signal processing.

[0046] There are many opportunities for adjusting the same two widely-varying parameters in more than one way. For example, one user interface modality (such as normal mouse operation) may be used for normal parameter adjustment, while a second user interface modality may be used for adjustments involving a different resolution, warping (i.e., logarithmic, gamma-corrected, arccosine, exponential, etc.), centering offset, etc. Another important case is where the same two widely-varying parameters are controlled with the same resolution, warping, offset, etc., but in a different user interface modality (e.g., a trackball or touchpad may have some advantages in certain situations over use of a traditional mouse). A more widely applicable example is that of responding to and preventing hand/wrist/arm fatigue and injury. A traditional mouse fitted with an additional user interface sensor allows a user to interchangeably enter information with either the mouse body or another user interface sensor, changing which user interface modality is used (obtaining the same results with either) to relieve fatigue or pain, or prevent injury.

[0047] More specifically, the addition of a user interface sensor provides many opportunities for alternative means of adjustment of a common pair of adjustable parameters. The user may benefit from having both adjustment modalities available, changing modalities as needed or desired. For example:

[0048] A user may simply switch between using the invention as a traditional hand-movable computer mouse and using the invention as another kind of user interface sensor.

[0049] The user may benefit from having both modalities available to avoid or in response to hand fatigue.

[0050] The user may also benefit from having both modalities available due to the type of pointing or data entry interaction needed—depending on the case, one type of modality may perform better than another.

[0051] The trackball, touchpad, or other user interface sensor apparatus may be used to provide alternative resolution modalities so that a user may switch between using the invention as a traditional hand-movable computer mouse to obtain one level of parameter adjustment resolution and using the invention as a user interface sensor to obtain a different level of parameter adjustment resolution.

[0052] The trackball or touchpad may be used to provide alternative warping modalities for the same pair of adjustable parameters so that a user may switch between using the invention as a traditional hand-movable computer mouse to obtain one type of parameter adjustment (for example, linear) and using the invention as another kind of user interface sensor to obtain a different type of

parameter adjustment resolution (for example, logarithmic, gamma-corrected, arccosine, exponential, etc.).

[0053] The user interface sensor may be used to provide alternative offset modalities for a common pair of adjustable parameters so that a user may switch between using the invention as a traditional hand-movable computer mouse to obtain one centering of parameter adjustment and using the invention as another kind of user interface sensor to obtain a different centering of parameter adjustment. These modalities can provide one or more “location bookmarks” for cursor location, each affiliated with a sub-context within an interactive application.

[0054] Further, the addition of another user interface sensor provides many opportunities for the simultaneous adjustment of additional parameters that may or may not require simultaneous interactive control. The traditional computer mouse may be used to simultaneously adjust two parameters while the additional user interface sensor may be configured to allow the fingers to simultaneously adjust at least two additional parameters. In some applications, these additional parameters may be closely related to those assigned to the traditional computer mouse. For example, the traditional computer mouse may be used to simultaneously adjust the location within a window of a text, graphic, or other object, while the additional user interface sensor allows the fingers to be used to adjust the type or attributes of the text, graphic, or other object. In other applications, these additional parameters may be of a different isolated context from those assigned to the traditional computer mouse. For example, the traditional computer mouse may be used to simultaneously adjust two parameters dealing with affairs within an active application window, while the addition of another user interface sensor allows the fingers to be used to adjust at least two additional parameters dealing with broader window system affairs such as vertical and horizontal scrollbars, window selection, window resizing, etc., or intermediate-level affairs such as zoom control, help-window navigation, clip-art selection, etc. Another application would be to provide separate adjustment of selections for “cut” or “copy” operations from the adjustment of insertion location or selection for a “paste” operation.

[0055] In instances of the invention involving the addition of a touchpad, the touchpad may be configured and/or enhanced to allow the fingers to adjust three or more additional interactive measured parameters. These additional interactive measured parameters may be assigned to control more sophisticated interactive affairs such as 3-dimensional space position, 3-dimensional space orientation, color model navigation, image or audio processing parameter settings, etc.

[0056] The additional interactive measured parameters (above the two typically associated with traditional touchpads) may be provided in a number of ways. For example, the touchpad may be a relatively low-cost null-contact touchpad that has been adapted to measure at least one maximum spatial span of contact in a given direction. The user may also control an additional parameter by varying the width between the spatial extremes of a single point of contact (i.e., how much finger flesh makes contact with the pad) or multiple points of contact (i.e., the spread between two contacting fingers). As there are two geometrically orthogonal sensing directions on a touchpad, this provides the user with a method for controlling four total parameters from a touchpad. Further, rotational transformations or other methodologies may

be used to measure the angle of rotation of an oblong contact profile. The measured angle may be used as a fifth interactive parameter, and/or used to adapt the measurement of maximum spatial span of contact in an arbitrary angle. The null-contact touchpad may be further adapted to measure pressure applied to the null-contact touchpad via, for example, use of an attached pressure sensor. The pressure may be used as a sixth interactive parameter, and may or may not have rapid pressure changes recognized as ‘tap’ or ‘click’ events.

[0057] Another way to provide the additional interactive measured parameters (above the two typically associated with traditional touchpads) with a touchpad is to implement the touchpad with a pressure sensor array. Through use of operations effectively amounting to image processing, a pressure sensor array touchpad can be adapted to measure the rocking position of a contacting finger in two orthogonal directions, as well as the rotational position and average pressure of a contacting finger. Thus a pressure sensor array touchpad can be adapted to provide up to six widely variable interactive adjustable parameters from the contact of a single finger. A pressure sensor array touchpad can be further adapted to measure parameters relating to a plurality of contacting fingers.

[0058] All of these considerations and others demonstrate the potential value in providing the addition of another user interface sensor to a traditional hand-movable computer mouse. In the descriptions to follow, various implementations and exemplary applications of exemplary embodiments are considered and explained.

1. Exemplary Signal Flow and Processing

[0059] The invention provides for a wide range of signal flow and processing configurations and implementations. FIGS. 1a-1i illustrate various exemplary implementations involving merging, selecting, multiplexing, and preprocessing distributed in various ways between the body of the user interface device and an associated piece of equipment. FIGS. 1a-1d concern the aggregated pair of user interface sensors in isolation, while FIGS. 1e-1i address arrangements where some functions of the invention are performed in the associated external equipment. It is noted that the invention further provides for any of these exemplary functionalities, as well as other functionalities, to be combined or made selectable. In any of the exemplary implementations disclosed herein, power may be supplied to these implementations by the associated external equipment or by other devices such as batteries, storage capacitors, photoelectric devices, and the like.

[0060] FIG. 1a shows an implementation 100a featuring two user interface sensors 101, 102, each of which may be a particular type of user interface sensor (which again may be a trackball, touchpad, mouse, or other user interface device) that can be collocated within the common physical enclosure 100 (demarcated by the dotted-line boundary). First user interface sensor 101 produces signal 108 and second user interface sensor 102 produces another signal 109, which are directed to a merge or select function 103. The merge or select function produces outgoing signal 110 which is provided to associated external equipment. Here signals 108, 109 (from first and second user interface sensors 101, 102) would typically lose their individual identities within the outgoing signal 110 and as such may be used or processed interchangeably (without individual attribution to either the first or second user interface sensor) by the associated external equipment.

[0061] Merge or select function 103 may take several forms in various implementations. For example, in one embodiment it may simply be fixed to only perform a merge operation. In another embodiment it may only provide a selection function; here the selection function may be controlled by the user using a switch or some sort of action, or the selection may be remotely controlled by external equipment. As an alternative, merge or select function 103 may instead provide a user adjustable “merge” or “select” function.

[0062] FIG. 1b shows an implementation that is similar to that of FIG. 1a. The primary difference is that the FIG. 1b implementation 100b replaces merge or select function 103 of FIG. 1a with multiplex function 104 to produce outgoing signal 110. Here signals 108, 109 (from first and second user interface sensors 101, 102) retain their individual identities within outgoing signal 110 and as such may be used or processed separately by the associated external equipment.

[0063] FIG. 1c shows implementation 100c which is similar in many respects to that of FIG. 1a. However, the FIG. 1c embodiment utilizes preprocessor 105 applied to signal 109 to produce processed signal 109a. The processed signal 109a, along with signal 108, is directed to merge or select function 103, resulting in outgoing signal 110. Preprocessor 105 may thus introduce a pre-processing step (such as resolution modification, warping modification, offset modification, etc.) on signal 109 to produce a signal of distinguished value from that of signal 108.

[0064] FIG. 1d illustrates another exemplary implementation 100d which is similar to that of FIG. 1c but with an additional preprocessor 106 applied to signal 108. Preprocessor 106 produces processed signal 108a, which along with signal 109a, is directed to merge or select function 103 to produce outgoing signal 110. Preprocessor 106 may therefore introduce a pre-processing step (such as resolution modification, warping modification, offset modification, etc.) on signal 108 to produce a signal of either equivalent or distinguished value from that of signal 109a.

[0065] FIG. 1e shows implementation 100b of FIG. 1b (which features two user interface sensors 101, 102 and a multiplex function 104 producing an outgoing signal 110) used in conjunction with subsequent functions provided by associated external equipment 150a. These subsequent functions are shown within the functional boundary 150 of the associated external equipment 150a.

[0066] Outgoing signal 110 from the common physical enclosure 100, is presented to demultiplexer 117 within external equipment 150a. Demultiplexer 117 produces signal 118 corresponding to or associated with pre-multiplexed signal 108, and an additional signal 119 corresponding to or associated with the pre-multiplexed signal 109. Here, signals 118, 119 are presented to merge or select function 113 producing merged or selected signal 120. This implementation is functionally similar or equivalent to that of FIG. 1a except that the various types of merge or selection functions 103 are provided within the associated external equipment 150a (for example in software, perhaps within an application where it is customized for the needs of that application) rather than being provided within physical unit 100b.

[0067] FIG. 1f shows implementation 100b of FIG. 1b used in conjunction with subsequent functions provided by associated external equipment 150b, and similar to that of FIG. 1e, except signal 119 produced by demultiplexer 117 is directed to preprocessor 115 to produce processed signal 119a before being sent to merge or selection function 113. This imple-

mentation is thus functionally similar or equivalent to that of FIG. 1c except that the various types of merge or selection 103 and preprocessor 105 functions in FIG. 1c are provided within the associated external equipment 150b (for example in software, perhaps within an application where it is customized for the needs of that application) rather than being provided within the physical unit 100b.

[0068] FIG. 1g shows implementation 100b of FIG. 1b used in conjunction with subsequent functions provided by associated external equipment 150c. This arrangement expands on that shown in FIG. 1f in that signal 118 produced by demultiplexer 117 is directed to preprocessor 116 to produce processed signal 118a. The processed signal is then sent to merge or selection function 113. This implementation is thus functionally similar or equivalent to that of FIG. 1d except that the various types of merge or selection 103 and preprocessor 105, 106 functions in FIG. 1d are provided within the associated external equipment 150c (for example in software, perhaps within an application where it is customized for the needs of that application) rather than being provided within the physical unit 100b.

[0069] FIG. 1h shows implementation 100b of FIG. 1b used in conjunction with subsequent functions provided by associated external equipment 150d. Here again, as in the arrangement of FIG. 1f, signal 119 produced by demultiplexer 117 is directed to preprocessor 115 to produce processed signal 119a. In contrast to other embodiments, processed signal 119a is not directed to merge or selection 113 function and retains its identity for use by a different destination from that of signal 118 within associated external equipment 150d.

[0070] As a final illustrative example in this series, FIG. 1i shows implementation 100b of FIG. 1b used in conjunction with subsequent functions provided by associated external equipment 150e. Here, as in the arrangement of FIG. 1g, signals 118, 119 produced by demultiplexer 117 are directed to preprocessors 115, 116 to produce processed signals 118a, 119a. In contrast to other embodiments, processed signals 118a, 119a are not directed to merge or selection 113 function and thus retain their identity for use by differing destinations within associated external equipment 150e.

[0071] Having presented various exemplary signal flows and processing realizations provided for by the invention, attention is now directed to exemplary implementations utilizing specific types of user interface sensors. It is to be understood that the various sensors, techniques and methods disclosed herein may be implemented using computer software, hardware, and firmware, and combinations thereof.

2. Implementations Utilizing Specific Types of Additional User Interface Sensors

[0072] In this section, a number of exemplary implementations of the invention utilizing various types of additional user interface sensors added to an original user interface sensor or device. The first three sections address cases where the original user interface sensor is a movable mouse and the additional user interface sensor is a trackball, touchpad, or other exemplary technology, including additional scroll-wheels. Then exemplary adaptations of trackballs and touchpads, each traditionally used to provide simultaneous adjustment of two interactive widely-varying parameters, are extended to provide simultaneous adjustment of as many as six interactive widely-varying parameters and other forms of control. This section continues by presenting exemplary implementations

where the original user interface sensor is not a mouse, where there are a plurality of additional user interface sensors, where there is a visual display or auditory output, where the additional user interface sensor is a removable module, and where the implementation itself is a removable module.

[0073] 2.1 Trackball Implementations of Additional User Interface Sensors

[0074] FIGS. 2a-2c illustrate a number of implementations provided for by the invention where a trackball controller is used as an additional user interface sensor apparatus incorporated into a traditional hand-movable computer mouse. In each of these implementations it is understood that the trackball may be freely operated without disturbing previous or currently-varying parameter adjustments made by the mouse.

[0075] In one implementation, a trackball controller is added to the top surface of a conventional computer mouse as depicted in FIG. 2a. The conventional mouse buttons may be located in various places in view of the presence of the trackball and in synergy with it. In the configuration depicted in FIG. 2a, buttons 201 and 202 are located on the surface of mouse 200; button 201 being on the left of the trackball and button 202 being on the right of the trackball.

[0076] In a second configuration depicted in FIG. 2b, buttons 231 and 232 are now separated and located on the sides of mouse 230 as is the case with many trackball interfaces; button 231 being on the left side of mouse 230 and button 232 being on the right side of the mouse.

[0077] In a third possible configuration depicted in FIG. 2c, elongated buttons 261 and 262 are shown located on the surface of the mouse 260; button 261 wraps around the left of the trackball and button 262 wraps around the right of the trackball. The elongated buttons 261 and 262 may be positioned so that a user can readily and rapidly move fingers from trackball 265 to buttons 261 and 262, or even operate one of these buttons with one finger while another finger contacts trackball 265.

[0078] It is noted that unlike the touchpad described below, the trackball has an effectively unconfined range of contiguous data entry.

[0079] 2.2 Touchpad Implementations of Additional User Interface Sensor

[0080] FIGS. 3a-3c illustrate a number of exemplary implementations provided for by the invention where a touchpad controller is used as an additional user interface sensor incorporated into a traditional hand-movable computer mouse. In each of these implementations it is understood that the touchpad may be freely operated without disturbing previous or currently-varying parameter adjustments made by the mouse.

[0081] In one implementation, trackball 205 in FIG. 2a can be replaced with touchpad 305 as shown in FIG. 3a. Additionally, this touchpad implementation can also support the alternative button configurations of FIGS. 2b and 2c. By way of illustration, FIG. 3b shows buttons 331, 332 positioned on either side of the mouse body 330, while FIG. 3c shows elongated buttons 361, 362 on the surface of the mouse wrapping around either side of touchpad 365.

[0082] It is noted that unlike the trackball, the touchpad typically has a confined maximum range of data entry by contiguous operation of a finger, stylus, etc.

[0083] 2.3 Other Implementations of Additional User Interface Sensors.

[0084] In accordance with other embodiments, the invention provides for still other types of additional user interface

sensors. In each of these embodiments it is understood that any of these user interface sensors may be freely operated without disturbing previous or currently varying parameter adjustments made by the mouse or other associated device.

[0085] As a first example, an X-Y joystick may be used in place of the trackball or touchpad described above. The joystick may have a spring-return or may retain the last position it was placed. Similar to the touchpad and unlike the trackball, the X-Y joystick typically has a confined maximum range of travel.

[0086] As another example, two or more scrolling finger wheels may be used in place of the trackball or touchpad described above. The scrolling finger wheels may be implemented with an unconfined maximum range of travel similar to the trackball, or with a confined range of travel like the touchpad and X-Y joystick. In this embodiment, it may be advantageous to have one or more finger scroll-wheels mounted with its adjustment direction perpendicular to that of another finger scroll-wheel so that each wheel may be appropriately associated with vertical and horizontal scroll bars of a window, or other useful orthogonally-based user interface metaphor. For example, looking ahead to FIGS. 10a and 10b, embodiments 1000 are depicted comprising the usual components of a scroll-wheel mouse (mouse body 1001, buttons 1011 and 1012, and the usual scroll wheel 1021) complemented with an additional scroll wheel 1022 with adjustment direction perpendicular to that of finger scroll-wheel 1021.

[0087] As another example, two or more rotating control knobs may be used in place of the trackball or touchpad described above. Like the scrolling finger wheels, the rotating control knobs may be implemented with an unconfined maximum range of travel like the trackball or with a confined range of travel like the touchpad and X-Y joystick.

[0088] The invention also provides for more exotic types of user interface sensor technologies—for example, proximity detectors of various types (RF, infrared, etc.), video cameras (using any of the techniques provided in U.S. Pat. No. 6,570, 078), and other emerging and unforeseen technologies—to be used as the additional user interface sensor aggregated in the same physical enclosure as the first user interface sensor.

[0089] 2.4 Larger Numbers of Interactively Widely-Varying Adjustable Parameters from the Additional User Interface Sensor

[0090] In accordance with embodiments of the invention, additional user interfaces may be used to capture larger numbers (i.e., more than two) of widely-varying adjustable parameters from the additional user interface sensor. Some examples are provided here, but many others are possible as may be readily understood by one skilled in the art.

[0091] FIGS. 4a-4d address the case of the trackball. FIG. 4a illustrates a freely-rotating trackball 205 and the two principle orthogonal adjustment directions 401,402 that are responsively resolved and measured in traditional trackball user interface devices. However, at least two other physical degrees of freedom may be readily exploited, and at least six total parameters can be interactively adjusted and measured. FIG. 4b shows the application of downward pressure 403 on trackball 205. Such pressure 403 may be applied without disturbing current values established in orthogonal adjustment directions 401, 402. Further, the trackball may be implemented so that downward pressure 403 may be applied while simultaneously adjusting trackball 205 in orthogonal adjustment directions 401, 402, particularly if the signal produced by the measurement of downward pressure 403 incorporates

a modest “grace” zone of non-responsiveness for light pressure values. Downward pressure impulses may alternatively be sensed and treated as discrete event “taps,” as commonly used in contemporary touchpad interfaces found in laptop computers, for example.

[0092] FIG. 4c shows the application of “yaw” rotation 404 (i.e., rotation around the vertical axis) of trackball 205. This yaw rotation 404 may be applied without disturbing current values established in orthogonal adjustment directions 401, 402 and can be readily measured and adjusted as a widely-varying parameter. Further, by grasping trackball 205 (or other operational methods), the yaw rotation 404 and traditional orthogonal adjustment directions 401,402 may be independently and simultaneously adjusted. It is also noted that in principle up to six widely-varying physical degrees of freedom can be simultaneously measured from a properly configured trackball 205 by placing the trackball 205 in a cradle that senses not only downward pressure 403 or displacement but also lateral pressure or displacement. As shown in FIG. 4d, both forward-backward, non-rotational force 405 and left-right, non-rotational force 406 may be applied to the trackball in a manner that the values of force or displacement in each of these directions 405,406 can be independently measured. Thus, by grasping trackball 205 (or other operational methods), three rotational directions of orientation 401, 402,404 and three non-rotational directions of force or displacement 403, 405,406 may be independently and simultaneously adjusted by a user and measured as six independent interactively adjustable user interface parameters. These correspond, effectively, to measurable adaptations of the six degrees of freedom of an orientable object in 3-dimensional space as found in classical mechanics and aeronautics—that is:

[0093] “roll” rotation (adapted to 401)

[0094] “pitch” rotation (adapted to 402)

[0095] “up-down: displacements (adapted to 403)

[0096] “yaw” rotation (adapted to 404)

[0097] “forward-backward” displacements (adapted to 405)

[0098] “left-right” displacements (adapted to 406).

[0099] Most trackball sensing technologies use optically based techniques for sensing the two traditional components of rotation (“roll” and “pitch”) of the trackball. The trackball itself may be configured with an optical pattern on it with spatially varying reflectivity for a range of the light spectrum. The pattern may be such that it can spatially vary light reflectivity in these two traditional components of trackball rotation. Alternatively, two spatially varying reflectivity patterns, each active at different ranges of the light spectrum or light polarization, may be superimposed or integrated with the trackball.

[0100] A number of approaches may be used to obtain measurements for all three directions of rotation. In one completely optical approach, a second or third spatially varying reflectivity pattern active at, respectively, a second or third portion of the light spectrum (or light polarization if available) may be superimposed or integrated with the patterns employed for traditional “roll” and “pitch” rotation sensing, and an additional optical source and sensor is used to obtain measurement of the added varying reflectivity pattern. Depending on the pattern(s) used, sensor signals may be directly usable or may require processing of the three primitive signals measured by the sensors to obtain a clean decomposition of the measurement signals into independent “roll,”

“pitch,” and “yaw” signals independently responsive to the “roll,” “pitch,” and “yaw” components of trackball rotation.

[0101] As another alternative, the trackball may include internally, or on its surface, or both, materials with spatially varying patterns of magnetic properties, capacitive properties, electromagnetic properties, ultrasonic acoustic properties, resonance phenomena of any of these properties, polarization phenomena of any of these properties, etc., individually or in combination, each of which may be active at specific ranges of polarization, frequencies, etc. These may be used together with or in place of optical measurement approaches. Again, depending on the pattern(s) used, sensor signals may be directly usable or may require processing of the three primitive signals measured by the sensors to obtain a clean decomposition of the measurement signals into independent “roll,” “pitch,” and “yaw” signals independently responsive to the “roll,” “pitch,” and “yaw” components of trackball rotation as is clear to one skilled in the art. It is also noted that the third component of rotation of the freely-rotating trackball may be interpreted or even measured as a discrete “click” event.

[0102] Similarly, a number of approaches may be used to obtain measurements for one, two, or three directions of non-rotational trackball displacement. For example, the trackball may be secured in a saddle allowing free rotation of the trackball but causing any displacement actions on the trackball to invoke displacements of the saddle. The saddle displacement may be measured with a displacement sensor which itself may comprise one or more pressure, optical, resistive, capacitive, magnetic, electromagnetic, continuous-range sensors, switches, etc. It is also noted that one or more components of displacement of the freely-rotating trackball may be interpreted or even measured as a discrete “click” event.

[0103] FIGS. 5a-5d turn now to the case of the touchpad. FIG. 5a illustrates touchpad 305 and the two principle orthogonal data entry directions 501, 502 that are responsively resolved and measured in traditional touchpad user interface devices. The touchpad shown in FIGS. 5a-5d, which provides at least four other physical degrees of freedom, may be implemented using the techniques presented in U.S. Pat. No. 6,570,078, for example.

[0104] FIG. 5b illustrates the use of downward pressure 503 in the context of a touchpad. In contemporary touchpad interfaces, such as those found in laptop computers for example, such downward pressure 503 is sensed and utilized as discrete event “taps.” However, downward pressure 503 may also be measured and adjusted as an independent and simultaneously interactive widely-varying parameter. Further, as illustrated in FIG. 5c, the rotational angle 504 of a finger contacting a touchpad with rough-elliptical contact boundary can also be measured as a widely-varying parameter. In FIG. 5d, both forward-backward 505 and left-right 506 components of the tilt of a contacting finger can additionally be measured as independent and simultaneously interactive widely-varying parameters.

[0105] The sensing of multiple fingers, the application of contact syntaxes and grammars, and other user interface control expansions of an adequately configured touchpad may also be achieved using, for example, the techniques presented in U.S. Pat. No. 6,570,078.

[0106] The invention also provides for larger numbers (i.e., more than two) of widely varying adjustable parameters from other types of user interface sensor technologies. In the case

of an X-Y joystick, the joystick may be configured to rotate on its axis, pulled in and out, fitted with a knob or trackball, etc., in a measurable fashion to provide additional and simultaneous interactively adjustable parameters. In the cases of finger scroll-wheels and rotational knobs, three or more of these devices may be provided. When implementing video cameras, known techniques for the extraction of additional parameters may be used. Examples of the various types of video extraction techniques that may be used are presented in U.S. Pat. No. 6,570,078.

[0107] 2.5 Non-Mouse User Interface Sensors

[0108] In one of its most abstract forms, the invention involves the incorporation of two conventional user interface sensors (such as a mouse, trackball, touchpad, joystick, etc.) into an embodiment where the user may freely use both of the user interface sensors individually or simultaneously with the same hand. As such, the invention provides for implementations that do not include a mouse as one of the user interface sensors. For example, two or more individual user interface sensors can be combined without need of a traditional hand-movable computer mouse. Such an implementation may be accomplished by implementing one of the possible user interface sensors in place of the traditional hand-movable computer mouse where taught in other descriptions of the invention. This configuration may be useful when built into a laptop computer, control console, musical instrument, and test instrument, among others.

[0109] In one exemplary implementation of a non-mouse embodiment, a trackball and touchpad may be arranged in the same physical enclosure so that the front, middle, or back of the palm may freely operate a conventional trackball while one or more selected extended or arching fingers may simultaneously or alternatively operate a touchpad. In this example, the touchpad may be a conventional touchpad providing two widely-varying simultaneously interactive parameters from a single finger contact, or the touchpad may be a more enhanced version providing as many as six widely-varying and simultaneously interactive parameters from a single finger contact. The touchpad may also be configured to accept multiple points of contact, recognize gestures, support syntax and grammatical constructions using, for example, the teachings provided by U.S. Pat. No. 6,570,078.

[0110] In another non-mouse implementation, two trackballs may be arranged in the same physical enclosure. In one possible arrangement, the two trackballs may be positioned so that they lie parallel to the length of the hand, enabling the front, middle, or back of the palm to freely operate a first trackball while one or more extended or arching fingers may simultaneously or alternatively operate the second trackball.

[0111] In another arrangement, the two trackballs may be positioned so that they lie parallel to the width of the hand, so that the fingers and/or thumb on the left side of the hand may operate a leftmost trackball while the remaining fingers and/or thumb on the right side of the hand may individually or simultaneously operate a rightmost trackball. In each of these arrangements, either or both of the trackballs may be a conventional trackball providing two widely-varying and simultaneously interactive parameters, or it may be a more enhanced trackball providing as many as six widely-varying and simultaneously interactive parameters as described earlier.

[0112] In addition to the just-described embodiments, alternative arrangements, such as the combination of a palm-operated trackball and a recessed joystick, and others, are also provided for by the invention.

[0113] 2.6 Use of More than One Additional User Interface Sensor

[0114] Typically the arrangements of two non-mouse user interface sensors described above in Section 2.5 can also be applied to embodiments of the invention where a mouse user interface sensor is used. In such embodiments, a mouse user interface sensor is supplemented with at least two additional user interface sensors ergonomically arranged so that the two additional user interface sensors may be simultaneously or alternatively operated by the same hand. If these embodiments are further configured so the mouse body is readily moved with adequate precision via the back of the operating hand, then all three user interface sensors may be simultaneously or alternatively operated by the same hand in an ergonomically advantageous manner.

[0115] FIGS. 14a-14d illustrate some exemplary embodiments of the just-described features. FIG. 14a illustrates a mouse where traditional mouse buttons have been replaced by trackballs 1405a, 1405b. These trackballs 1405a, 1405b may accept a downward pressure impulse and as such act as the traditional mouse buttons. However, trackballs 1405a, 1405b are also adjustable and each readily provides two or more additional widely-variable and simultaneously adjustable parameters in addition to the two parameters adjusted by moving the mouse body 1400.

[0116] FIG. 14b shows a similar arrangement where traditional mouse buttons have been replaced by touchpads 1435a, 1435b. If desired, these touchpads may accept a downward pressure impulse and as such act as traditional mouse buttons, but are also adjustable as touchpads and as such each readily provides two or more additional widely-variable and simultaneously adjustable parameters. As described in Section 2.5, a single hand may be positioned to comfortably operate simultaneously or alternatively both trackballs or both touchpads. If these embodiments are further configured so the mouse body is readily moved with adequate precision via the back of the operating hand, then either of these embodiments readily provides six to twelve widely-variable and simultaneously adjustable parameters.

[0117] Other configurations are of course possible. For example, the configurations of FIGS. 14a and 14b may be blended as depicted in FIG. 14c, or in its mirror image. As another example, FIG. 14d illustrates a more extreme realization comprising a left-fingers/thumb trackball 1465a, a right-fingers/thumb trackball 1465b, a palm trackball 1465c, and a traditional clickable scroll-wheel 1468. Yet another alternative is to replace one or more of the trackballs of the FIG. 14d embodiment with a touchpad user interface sensor.

[0118] 2.7 Incorporation of Visual Display and Auditory Output

[0119] If desired, any of the mouse and non-mouse embodiments may further include a visual display. The visual display may provide details of adjustable parameter values, operation modalities, etc. The visual display may be physically associated with a physical enclosure (such as that of a traditional computer mouse), or may be displayed on the computer screen or display of other associated equipment.

[0120] Alternatively or additionally, any of the mouse and non-mouse embodiments may further provide auditory output. The auditory output may provide details of adjustable

parameter values, operation modalities, error conditions in usage of the invention, a condition relating to elapsed time or other metric of consistent use of a single usage modality, etc. The auditory output associated with the invention may be physically associated with a physical enclosure (such as that of a traditional computer mouse), or may be produced by speakers or headsets affiliated with the computer or other associated equipment.

[0121] 2.8 Provisions for Field Installation or Replacement of Additional User Interface Sensor

[0122] The invention also provides for the user interface sensor to be implemented using a replaceable module accepted by an adaptation of a traditional computer mouse. In this implementation a user may initially obtain the invention in one configuration and field modify it to another configuration.

[0123] 2.9 Implementation as a Module Removable from Affiliated Equipment

[0124] The invention also provides for a traditional computer mouse to be implemented as a removable module in a laptop computer or other affiliated equipment, and may include a wireless link with such devices. In particular, this removable module may further include one or more user interface sensors, with these sensors operable as a traditional trackball or touchpad when the invention is stowed in the laptop computer or other affiliated equipment in such a way that the invention's traditional hand-movable computer mouse modality is unmovable and hence unusable.

3. Exemplary Applications

[0125] Departing now from the range of extreme realization and embodiments of the invention, attention is directed towards particular applications of the invention. A number of examples of various embodiments of the invention in a wide range of applications will now be presented. Many of these applications are viable with only the simplest physical embodiments of the invention (for example, those suggested by FIGS. 2a-2c and 3a-3c). In the discussion that follows, particular note is directed towards the discussion in Section 3.3 involving FIGS. 8 and 9a-9b. Although the discussion is motivated by a graphical layout application, the principles of the discussion in Section 3.3 involving FIGS. 8 and 9a-9b are very general, and the discussion illustrates the power of the invention for various applications in almost directly quantifiable terms.

[0126] 3.1 Wrist/Hand/Arm-Fatigue Relief and Prevention Application

[0127] The danger and damage stemming from extensive continuous or mis-postured mouse usage to wrist, hand, and arms are sadly misfortunate and increasingly well recognized. As the present invention provides a plurality of different user interface sensors, it is well suited for use in responding to and preventing wrist/hand/arm fatigue due to overuse. In one exemplary implementation, user interface parameters can be interchangeably adjusted with either the movement of the mouse body or the use of an integrated trackball or touchpad with identical task results. Thus a user with a tiring hand can change at will the user interface sensor employed according to how the hand feels or the nature of a specific task. In addition, to prevent fatigue or injury, the user can also switch back and forth between moving the mouse body and using the trackball/touchpad either by free choice or by following auditory or visual prompting from a time or usage monitor.

[0128] 3.2 Double-Scrollbar Application

[0129] Contemporary mice often feature a small rotating wheel between the buttons for use in operating the vertical scroll bar of a window without changing the position of the mouse. In one particular application of the invention, the left-right sensing capability of the trackball or touchpad may be used to add a similar capability for horizontal scroll bars of a window.

[0130] In a trackball implementation, a user can move the vertical bar **611** of FIG. 6 up by rotating trackball **205** away from him/herself, or one can move the vertical bar **621** down by rotating trackball **205** towards him/herself. By rotating trackball **205** to the left, the user can move the horizontal bar **621** left. Similarly, the user can move the horizontal bar **621** right by rotating the trackball **205** to the right.

[0131] In a touchpad implementation, a user can move scroll bar **611** up by sliding the finger away from her/himself or move scroll bar **611** down by sliding the contacting finger towards her/himself; similarly, the user can move the scroll bar **621** left by sliding the finger to the left or move the scroll bar **621** right by sliding the contacting finger to the right.

[0132] In another implementation, the vertical and horizontal scroll bars may be adjusted with a conventional scroll-wheel mouse that has been fitted with an additional scroll-wheel. FIGS. **10a** and **10b** depict exemplary embodiments **1000** of such an arrangement which comprise the usual components of a scroll-wheel mouse including mouse body **1001**, buttons **1011** and **1012**, and traditional scroll wheel **1021**, with these components further complemented by an additional scroll wheel **1022** with adjustment direction perpendicular to that of finger scroll-wheel **1021**. FIG. **10a** illustrates an arrangement where the additional scroll-wheel is located closer to the user while FIG. **10b** illustrates an arrangement where the additional scroll-wheel is located farther away from the user. In each of these arrangements, the two scroll-wheels are shown co-centered with respect to the mouse body; for simultaneous adjustment it may be advantageous to locate the additional scroll-wheel **1022** to one side or the other of the centered positions shown in FIGS. **10a** and **10b**. One approach useful for supporting both left-handed and right-handed users, which may provide additional utility, would be to provide two off-centered additional scroll-wheels, one on either side of the center line of the mouse body **1001** and conventional scroll-wheel **1021**.

[0133] 3.3 Traditional 2D Layout, Cad, and Graphics Applications

[0134] In most contemporary 2-dimensional layout and graphics applications, such as those commonly used for viewgraphs, page layout, electronic CAD, etc., numerous mouse operations are necessary for each of the many types of object attribute modification, etc. Typically, these mouse operations are required because the mouse only allows for the interactive adjustment of two widely-varying parameters at a time, and the user must change context several times as the parameters adjusted by the mouse are chosen, adjusted, and then replaced with another pair of parameters. The present invention is useful in many of these circumstances because it allows for more than two parameters to be adjusted at the same time.

[0135] FIG. 7 shows an example of a session involving the authoring of a viewgraph. The viewgraph authoring task showcased in this example includes the creation of a flowchart diagram (here depicting a business workflow process) and as such also illustrates related needs and attributes of a 2D CAD program involving layout of a diagram (such as a cir-

cuit, algorithm, etc.) or physical object (such as a PC board, control panel, semiconductor photolithography mask, etc.). In that this example further involves drawing, the example also illustrates the related needs and attributes of a paint-box or electronic drafting application.

[0136] In this broadly representative application, application window **700** is shown comprising menu area **700a** and drawing area **700b**. Within the drawing area, viewgraph title **701** and portion **702** of the flowchart to be drawn, comprising thus far a sequence of flowgraph objects connected by arrows, have already been entered and rendered. New flowgraph objects may be introduced in standard fashion by selecting the type of new object desired from a palette, initially putting an instance of the selected object type in a convenient place in the drawing area, adjusting the size, orientation, color, and/or other attributes, and putting into final position. Often a number of the last few steps are interactively cycled through multiple times before the newly introduced object is adequately drawn and the user directs their attention to the next task. In this example, the palette of available objects of a specific high-level task is shown as an overlapping stack of three sub-class palettes **703a**, **703b**, **703c**, each providing a selection of available objects within that sub-class. Here, for example, sub-class palette **703a** has been selected (as indicated by the heavy line) from other available objects **705**, within the sub-class palette **703a**. Upon selection, an initial highly adjustable rendering of a specific instance **714** of the selected object **704** appears in a convenient location, which may be selected by the user.

[0137] The specific instance **714**, rendered in this highly adjustable initial state, is typically surrounded by graphical handles **716** which facilitate sizing, positioning within the drawing area, and often at least rotational orientation (for example, using the mouse with the ALT key simultaneously held down to interactively adjust the angle of rotation of the object should that be needed). Traditionally, the cursor controlled by the mouse **717** can be moved within object **714** to relocate it within drawing area **700b** or can, as shown in FIG. 7, be positioned atop one of the graphical handles **716** to permit the mouse to adjust the horizontal and vertical scale of object **714**, i.e., adjust its size and aspect-ratio. In some application packages, the latter adjustment is permitted to collapse the object through to 'zero' thickness in one of the adjustment dimensions and continue through to re-render the object in mirror image, thus additionally providing a form of vertical and horizontal flip by using the size and aspect-ratio resizing.

[0138] As familiar and widely accepted as these sorts of operations are, there is considerable overhead involved in such sequences of repeated selecting and adjusting (and in some cases additional deselecting) pairs of parameters from a larger collection of parameters. To see several aspects of the power of the present invention, these operations are now examined in more detail in generalized form.

[0139] FIG. 8 is a flowchart showing tasks involved in selecting and adjusting one of a plurality of available pairs of adjustable parameters by using a user interface device permitting the adjustment of only one pair of parameters at a time. In FIG. 8, the task goal is simply to adjust a pair of selected parameters **801** from a larger group of adjustable parameters. However, since a larger number of parameters are available for adjustment than are available at one time with the user interface sensor, the specific pair of parameters must first be selected. In most known graphical user interface systems and methods, this typically involves first using the user

interface device to control the movement of a cursor to a selection area of the graphical interface in a first overhead step **811** and then selecting the adjustment context (parameter pair) in a second overhead step **821**.

[0140] In some situations the selected pair of parameters may be immediately adjusted in goal operation **801**, but typically the cursor must then at least be moved, in a third overhead operation **812**, to a location outside of the selection area affiliated with operations **811** and **821** to another location (such as a drawing or typing area) affiliated with the context (parameter pair) that has just been selected for adjustment. In some situations the selected pair of parameters may be immediately adjusted in goal operation **801**, but typically the context must be activated (for example, by clicking in an open portion of a drawing area or selecting an existing object) in a fourth overhead operation **822**.

[0141] After the selected pair of parameters are adjusted (for example, by sizing a rectangle, etc.) the cycle may then immediately be repeated in some variant form for another pair of parameters, but typically the parameters must be deselected (for example, by another click to set the final value) in a fifth overhead operation **823** before the cursor may be moved to the selection area in another instance of operation **811**. In summary, in order to adjust one pair of parameters from a larger group of parameters, as many as five overhead operations (as many as two cursor movements **811**, **812** and as many as three select/deselect clicks **821**, **822**, **823**) are commonly required.

[0142] FIGS. **9a-9b** show broader implications of the overhead called out in FIG. **8**. FIG. **9a** depicts the sequential adjustment of pairs of parameters chosen from a larger group of pairs of parameters in a scenario suggestive of no interactive iteration. One pair of parameters is adjusted with up to five overhead operations in action **901**, then a second pair of parameters is adjusted with up to five overhead operations in action **902**, then a third pair of parameters is adjusted with up to five overhead operations in action **903**, and so on. Here the overhead slows things down but may not be a significant encumbrance to the broader goal of actions **901**, **902**, **903**, etc.

[0143] In contrast, FIG. **9b** depicts an interactive adjustment of pairs of parameters from a larger group of parameters in a scenario suggestive of one where interactive iteration is required, as the setting of one pair of parameters is difficult to complete without setting other parameters. Here the overhead is likely a significant encumbrance to the higher goal involving the pair-wise adjustment actions **901**, **902**, **903**, etc. For example, consider the interactive adjustment of six parameters, one pair at a time, through pair-wise adjustment actions **901**, **902**, **903**; not only are up to five operations of overhead involved for each of the pair-wise adjustment actions **901**, **902**, **903**, but a considerable extra number of passes must be made through these pair-wise adjustment actions **901**, **902**, **903** due to the fact that the adjustment of some parameters depends on or interacts heavily with the values of other parameters. The situation gets even more cumbersome should additional pair-wise adjustment operations be required. FIG. **9b** further shows the potential for one or more additional adjustment actions **950** which in principle may be iterated as well as and combined with pair-wise adjustment actions **901**, **902**, **903** (as suggested by fully-connected iteration paths **921**, **922**, **923**). In contrast to such sequences or iterative graphs of pair-wise adjustment actions, the present invention readily offers, for example, four, six, eight or even higher numbers of simultaneously adjustable parameters control-

lable by the same hand, which, when selected in a context, eliminate the many overhead operations depicted in FIGS. **8** and **9a-9b**, and the many additional iteration steps depicted in FIG. **9b**.

[0144] Returning now to the generalized graphical layout situation described earlier and depicted in FIG. **7**, the following operations are routinely performed in 2D graphics, layout, and CAD applications:

[0145] A. Selection of palette containing object;

[0146] B. Selection of object from palette;

[0147] C. Selection of "layer" object is to be assigned to (common in CAD, but typically not used in standard draw and paint packages);

[0148] D. Adjustment of object placement in drawing;

[0149] E. Adjustment of object sizing;

[0150] F. Adjustment of object rotation;

[0151] G. Adjustment of object line thickness(es);

[0152] H. Adjustment of object line color(s);

[0153] I. Adjustment of object fill color(s); and

[0154] J. Adjustment of object fill pattern(s);

[0155] Of these, operations B, D, and E are almost always utilized, operations A, G, and I are frequently utilized, and operations C, F, H, and J are rarely utilized.

[0156] Thus, in one exemplary application of the invention, it may be advantageous to group specific collections of operations that are commonly used together (this may be application specific) so that the benefits of having four or more widely-adjustable interactive parameters simultaneously available can be applied to speed the execution of basic common operations. For example:

[0157] Employing a four-parameter version of the invention:

[0158] Operation 1: Mouse for operation B

[0159] Operation 2: Mouse for operation D, trackball or touchpad for operation E

[0160] Employing a six-parameter version of the invention comprising a 4-parameter touchpad:

[0161] Operation 1: Mouse for operation B, touchpad finger-location for operation D, touchpad finger-tilt for operation E.

[0162] Employing a six-parameter version of the invention comprising a mouse and two trackballs or touchpads:

[0163] Operation 1: Mouse for operation B, first trackball/touchpad for operation D, second trackball/touchpad for operation E.

[0164] Other operations can be later applied in groupings and operations appropriate for the application.

[0165] As a possible alternative to the preceding example, it may be advantageous to assign a principal one of the user interface sensors to the sequential adjustment of each of such universal (or otherwise principal) operations and reserve the additional user interface sensors for rapid "in-context" interactive access to less frequently used operations. For example:

[0166] Employing a four-parameter version of the invention:

[0167] Operation 1: Mouse for operation B, trackball or touchpad for operation A and/or operation C;

[0168] Operation 2: Mouse for operation D, trackball or touchpad for operation E and/or operation F;

[0169] Operation 3: Mouse for operation G, trackball or touchpad for operation H; and

[0170] Operation 4: Mouse for operation I, trackball or touchpad for operation J.

[0171] Employing a six-parameter version of the invention comprising a 4-parameter touchpad:

[0172] Operation 1: Mouse for operation B, touchpad finger-location for operation A and touchpad finger-tilt for operation C;

[0173] Operation 2: Mouse for operation D, touchpad finger-location for operation E and touchpad finger-tilt for operation F;

[0174] Operation 3: Mouse for operation G, touchpad finger-location (and touchpad finger-tilt as useful) for operation H; and

[0175] Operation 4: Mouse for operation I, touchpad finger-location (and touchpad finger-tilt as useful) for operation J.

[0176] Employing a six-parameter version of the invention comprising a mouse and two trackballs or touchpads:

[0177] Operation 1: Mouse for operation B, first trackball/touchpad for operation A and second trackball/touchpad for operation C;

[0178] Operation 2: Mouse for operation D, first trackball/touchpad for operation E and second trackball/touchpad for operation F;

[0179] Operation 3: Mouse for operation G, first trackball/touchpad (and second trackball/touchpad as useful) for operation H; and

[0180] Operation 4: Mouse for operation I, first trackball/touchpad (and second trackball/touchpad as useful) for operation J.

[0181] As another alternative example, the user may freely assign user interface sensor parameters to operations A through J (and others as may be useful) for each of a number of steps as may match the task or tasks at hand. These assignments may be stored for later retrieval and use, and may be named by the user. The stored assignments may be saved along with specific files, specific applications, or as a general template the user may apply to a number of applications. It is noted that such variable assignments may be particularly useful to users as their hands fatigue, to prevent fatigue or injury, or as an adjustment for a temporary or permanent disability.

[0182] 3.4 Multi-Resolution Mouse Application

[0183] In another exemplary family of applications, one user interface sensor (for example, the mouse body) is used for course adjustment or fine adjustment of user interface parameters, while the additional user interface sensor (for example, a trackball or touchpad) is used for the remaining level of parameter adjustment resolution.

[0184] In most user-interface applications it is advantageous to have multiple scales of graphical user interface pointing and data entry. Many window systems provide an 'acceleration' setting which changes the pointing and data entry values on a more significant scale used for user interface changes made less frequently. Many applications further internally adjust the resolution as the corresponding visual display is "zoomed" in and out.

[0185] In many user interface applications, additional levels of resolution selection may be useful. For example, in pointing usage in text work, multiple resolutions would be advantageous in amending fine print or in making isolated changes in thumbnail overviews of 40% actual size or less. Similarly, in graphics work, fine resolution may be especially useful in making fine adjustments to figures. In the fine adjustment of figures, it may be further advantageous to

employ each of the separate user interface sensors in conjunction with corresponding snap-grids of differing grid spacing, particularly if one of the grid spacings is a sub-multiple of the other. A potentially useful extension of this would be to impose locally-applicable grid spacing on individual graphic or other objects, particularly objects which have been resized and hence for which the standard snap-grid spacing is no longer useful.

[0186] In a further application, the user interface may be directed towards non-positional adjustments, such as the adjustment of a rotation angle or of the color of a graphic object; here multiple resolutions may be valuable to make careful adjustments and coarse adjustments as needed. Similarly, scroll bars for long documents may also benefit from rapid access to multiple resolution scales, for example one user interface sensor may be used to navigate within a page (using a fine-grained navigation scale) while a second user interface sensor may be used to navigate across pages (using a coarser-grained navigation scale).

[0187] 3.5 Provision of Both Absolute and Relative Positioning

[0188] As discussed earlier, some types of user interface sensors, such as the touchpad and X-Y joystick for example, naturally have a limited maximum range of operation while others such as a mouse, trackball, and scroll-wheel have an essentially unlimited maximum range of operation. Although most user interface sensors are interpreted in relative terms (that is, the stimulus from the sensor is interpreted as a command to move a cursor, scroll bar, etc., incrementally in some direction relative to a current position), stimulus signals from any of these types of user interface signals may be interpreted in either a relative or absolute manner with varying degrees of naturalness or problematic qualities.

[0189] The present invention provides for one user interface sensor to be used for absolute positioning of a cursor, scroll bar, etc., or other means of parameter adjustment while another user interface sensor is used for traditional relative adjustment of such parameters. For example, a scroll bar may be adjusted in the usual fashion by a mouse body or trackball and in an absolute manner by a touchpad wherein the extreme values of the adjusted parameter correspond to the extreme positions at the edges of the touchpad. In one embodiment or application setting these two user interface sensors may control the same parameters—here it is often the result that the two sensors adjust the same parameters with different resolutions. Further, in this situation it is fairly likely that at least one of the resolution scale factors will be adjusted automatically. For example, in a document editor, as the number of pages of the document varies, the resolution of the absolute positioning sensor will correspondingly vary (so that the extremities in range of, for example, a touchpad correspond to the top of the first page and end of the last page) while the relative positioning sensor may retain the same incrementing/decrementing vertical scrolling resolution scale regardless of the number of pages.

[0190] 3.6 Color-Selection Application

[0191] In color adjustment, three parameters are involved in the full interactive span of any complete color space (RGB, HSB, YUV, etc.). By adding additional parameters to the overall user interface, all three parameters can be adjusted simultaneously rather than simply two at a time. As the present invention provides at least four simultaneous interactively adjustable parameters overall, it is thus potentially useful for fully interactive color adjustment within a complete

color space model. Further, should the additional user interface sensor be such that it alone provides three simultaneously interactively adjustable parameters, the first user interface sensor (for example, the mouse body) may be used as a pointer to select objects and the additional user interface sensor may be used to adjust attributes of the selected object such as its color, border color, etc.

[0192] 3.7 Multi-Level Graphic Object Grouping and Editing Application

[0193] In many drawing applications, lower-level graphical or other objects (such as lines, basic shapes, and text areas) may be grouped to form an aggregated object. This aggregated or “grouped” object (collectively referred to herein as an “aggregated object”) can then be moved, rotated, flipped, resized, etc. as if it were a lower-level graphic or other object. Grouping can also typically be done hierarchically and in mixed hierarchies, i.e., a plurality of lower-level graphical or other objects may first be grouped, and the resulting aggregated object may then itself be grouped with other aggregated objects and/or lower-level graphical or other objects.

[0194] Often one or more of the lower-level graphical or other objects comprising the aggregated object may need modification. In the case of text, most applications permit modifications to be made to individual text objects within an aggregated object. However, for any isolated adjustment to any other lower-level graphical or other object the aggregated object must be first disaggregated or “ungrouped” to completely free the involved lower-level graphical or other object from any grouping it had been involved in. After the modification, the grouping must be reconstructed. Often this becomes a cumbersome situation, particularly where the adjustments within the group are themselves an interactive response to other adjustments made within a drawing.

[0195] The additional number of widely-adjustable simultaneously interactive parameters made possible by the invention may be advantageously applied to this problem. For example, one user interface sensor may be used to navigate the levels of grouping and another user interface sensor may be used to perform operations on objects (lower level- or “grouped”) within that level of grouping of the overall aggregated object.

[0196] As an illustrative example, FIG. 11*a* shows a portion 1100 of a larger drawing, the portion 1100 featuring box 1101, two mowed lines 1111, 1112, and grouped object 1102 (here itself comprising two triangles connected by a line). In this example it is given that grouped object 1102 is itself grouped with box 1101 to form a second grouped object, and this second grouped object is itself grouped with the two arrowed lines 1111, 1112 to form a third grouped object. The user’s task is to modify FIG. 11*a* so that it becomes FIG. 11*b*. To do this, effectively the user must, in some order of operation:

[0197] Reposition grouped object 1102 from its original position in FIG. 11*a* to a new position in FIG. 11*b*;

[0198] Copy or otherwise reproduce grouped object 1102 to create an accompanying grouped object 1102*a*, and position it within box 1101;

[0199] Introduce a vertically distributed ellipsis 1103 and position it within box 1101—typically, a vertically distributed ellipsis 1103 is either rotated text or itself a fourth grouped object created from three aligned text elements; and

[0200] Ensure elements 1102, 1102*a*, and 1103 are in the end grouped with box 1101 to form the second grouped

object, and this second grouped object is itself grouped with the two arrowed lines 1111, 1112 to form a third grouped object.

[0201] Utilizing the invention, one user interface sensor is used to select the second group level, and the second user interface sensor is used to perform insert, copy, paste, and position operations within this level of grouping without any form or type of ungrouping operation. If the vertically distributed ellipsis 1103 itself is realized as a fourth grouped object created from three aligned text elements, when it is pasted into the drawing via this modality its 1103 grouping is subordinated appropriately (i.e., structured as a peer to grouped objects 1102, 1102*a*) within the second grouping level.

[0202] Although readily implemented using the novel user interface sensors described herein that make it particularly easy to simultaneously adjust a plurality of pairs of parameters, the aspects of the invention illustrated here can also be implemented with a conventional user interface sensor such as a traditional mouse, trackball, or touchpad. In this case, the conventional user interface sensor such as a traditional mouse, trackball, or touchpad must first be used to select the level of grouping and then be used to make the desired modifications within that level of grouping; to make modifications at a different level of grouping, the new level of grouping must be selected in a separate operation, thus adding overhead, as depicted in FIGS. 8 and 9*a-9b*. Although this novel ability to move and modify arbitrary graphic or other objects within groupings may be implemented in this way, having an additional number of widely-adjustable simultaneously interactive parameters—made possible by the main themes of the present invention—is clearly more efficient, as many or all of the overhead operations depicted in FIGS. 8 and 9*a-9b* can be eliminated via usage of the additional widely-adjustable simultaneously interactive parameters.

[0203] 3.8 3D Graphic Object Placement and Orientation Application

[0204] CAD and drawing packages that enable 3D object placement and orientation within a 3D space typically extend the capabilities of traditional 2D layout, CAD, and graphics applications as described in Section 3.3 to serve additional geometric needs. As illustrated in FIG. 12, the placement and orientation of 3D object 1200 within a 3D space 1250 (oriented with respect to a reference point 1251) requires that one additional position dimension and two additional orientation angles be specified to complete the full collection of three position dimensions 1201, 1202, 1203 and three orientation angles 1211, 1212, 1213.

[0205] To interactively adjust these parameters pairwise (or individually with a knob box as has been done historically in some systems) involves complex repetitive passes among high overhead operations as depicted in FIGS. 9*a-9b*, for example among steps 901, 902, 903. The necessity of making many high-overhead operations, for example moving among steps 901, 902, 903, can be functionally disruptive as well as slow and inefficient. The ability to interactively freely adjust the full collection of three position dimensions 1201, 1202, 1203 and three orientation angles 1211, 1212, 1213 is thus of extremely high value.

[0206] The invention provides for a wide range of mappings between the six position and orientation parameters 1201, 1202, 1203, 1211, 1212, 1213 involved in the placement and orientation of 3D object 1200 within a 3D space, and the large numbers of widely-adjustable and simulta-

neously interactive parameters facilitated by various realizations of the invention. As one example, a mouse fitted with two trackballs as in FIG. 14a may be used to specify these six parameters in various ways. One technique is to use the position of mouse body 1400 to control two of the position coordinates (for example 1202, 1203), one of the trackballs (for example 1405a) to control the orientation angles (1212, 1213) corresponding to these two axes, and the remaining trackball (1405b) to control the remaining axis (1201) and its corresponding orientation angle (1211). In this example, trackballs 1405a, 1405b are configured or used in 2-parameter modalities.

[0207] In another example, the mouse of FIG. 14a is fitted with two trackballs, the trackballs may be configured in 3-parameter modalities with one of the trackballs used for controlling three position dimensions 1201, 1202, 1203 and the second trackball configured to correspondingly control the three orientation angles 1211, 1212, 1213. Here the position of mouse body 1400 may be used to control other aspects of drawing operations.

[0208] In another implementation, a touchpad configured for 4-parameter operation involving two parameters of finger position and two parameters of finger tilt may be combined with a trackball configured for 2-parameter operation. In this example, finger position may be used to control two of the position coordinates (for example 1202, 1203), finger tilt may be used to control the orientation angles (1212, 1213) corresponding to these two axes, and the trackball to control the remaining axis (1201) and its corresponding orientation angle (1211). If the configuration includes a mouse body, its position may be used to control other aspects of drawing operations.

[0209] In another example, a configuration like that of FIG. 14d may use left-fingers/thumb trackball 1465a to control a first position coordinate 1201 and its corresponding orientation angle 1211, the right-fingers/thumb trackball 1465b to control a second position coordinate 1202 and its corresponding orientation angle 1212, and palm trackball 1465c to control third position coordinate 1203 and its corresponding orientation angle 1213.

[0210] The invention further provides for a wide range of additional mappings and geometric metaphors between the user interface sensor geometry and the three position dimensions 1201, 1202, 1203 and three orientation angles 1211, 1212, 1213 of a 3D object.

[0211] 3.9 Multiple Cursors and Cut and Paste Application

[0212] The invention additionally provides for a plurality of pairs of user interface sensor parameters to be used to control the respective positions of a corresponding plurality of individual cursors, selections, and/or insertion points. Multiple cursors and associated operations of multiple selection and insertion points can have many applications. Below, a few of these possibilities that would be apparent to one skilled in the art are showcased in a cut-and-paste editing example.

[0213] Cut, copy, and paste operations using traditional user interface devices usually involve multiple operations to switch between contexts introducing considerable overhead as depicted in FIGS. 9a-9b and 8. For instance, FIG. 13a illustrates a text editing example with text display window 1300 involving the selection of a clause 1320 (highlighted in this example) with the intention of relocating it to a new position 1351. In such an operation with a traditional 2-parameter mouse/trackball/touchpad user interface, the cursor is first used to select clause 1320 and then used to select the insertion position 1351.

parameter mouse/trackball/touchpad user interface, the cursor is first used to select clause 1320 and then used to select the insertion position 1351.

[0214] When writing or editing it is often the case that material needs to be fetched from elsewhere and put in the spot where one is currently writing. Here, the cursor is initially in the spot where the insertion is to occur and the user must then lose the cursor position currently set in this spot to go searching and then to select and cut or copy the material to be pasted; following this the user must then search again, perhaps taking considerable time, for said initial spot and re-establish the cursor location there. Equally often there are other situations where material must be split up and distributed in a number of far-flung places. Here, the cursor is initially in the spot where the material to be sequentially divided and relocated is originally aggregated; the user must repeatedly select the portion of the remaining aggregated material to be relocated and then lose that cursor position to go searching for the new destination insertion spot, perform the insertion, and then search again, perhaps taking considerable time, for the initial spot and re-establish the cursor location there. In both of these cases it would be advantageous if the user could “bookmark” an initial cursor location, search and perform the desired fetch or relocation operations, and readily return without search to the “bookmarked” location. Although this novel and advantageously valuable capability could be realized with a conventional mouse through context redirection operations involving the steps depicted in FIGS. 8 and 9a-9b, the present invention provides for a wide range of readily realized and easy-to-use implementations.

[0215] The invention may be used in a minimal configuration capable of interactively specifying at least two pairs of widely adjustable interactive parameters. Returning to the specific example associated with FIG. 13a, one pair of parameters is used to set the location of first cursor 1301 which is used in a selection operation, while the second pair of parameters is used to set the location of second cursor 1351 which is to be used to independently set an insertion point. The user may then perform the cut and paste operation with a single mouse click, resulting in the outcome depicted in FIG. 13b. The relocated text clause 1320 has been transferred to a position determined by the insertion cursor 1351 (here shown to the left of the cursor 1351; it could just as easily be to the right of it), and cursor 1301 used to make the selection remains in position. Either cursor 1301 or 1351 may now be moved and/or used for other cut, copy, paste, or (via the keyboard) new text insertion operations.

[0216] Although in this example the two cursor locations were close enough to be displayed in the same window 1300, the value of this application of the invention is significantly increased should the two positions be separated by many pages, many tens of pages, or even many hundreds of pages of text. Such situations may be handled by any number of approaches as is clear to one skilled in the art. In one approach involving a single display window, the area comprising the cursor whose corresponding user interface sensor was last manipulated is displayed in the single display window. In another approach involving a single display window, a click event or other user interface stimulus may be used to toggle among the areas comprising the various cursor locations. In yet another approach, at least two windows may be rendered, with one of the cursors displayed and operable within one window and a second cursor displayed and operable in a second window.

[0217] The invention also provides for these general principles to be applied to other types of objects and applications, such as spreadsheet cells (involving data, formula objects,

and cell formats), graphical objects, electronic CAD diagrams (where objects may be connected with formulas, dynamic models, etc.), and others as will be apparent to one skilled in the art.

[0218] 3.10 Simulation, Processing, and Analysis Applications

[0219] Simulation, processing, and analysis applications typically involve a large number of parameters which are adjusted to model, affect or investigate the resulting behaviors, end results, and/or implications. Conventional 2-parameter user interface devices such as a mouse/trackball/touchpad require the user to adjust these parameters pairwise (or individually with a knob box as has been done historically in some systems) involving complex repetitive passes among high-overhead operations as depicted in FIGS. 9a-9b, for example among steps 901, 902, 903. As in the case of 3D object positioning and orientation, the division among high-overhead operations, for example moving among steps 901, 902, 903, can be functionally disruptive as well as slow and inefficient. The ability to interactively and freely adjust larger collections of parameters simultaneously is thus also of extremely high value.

[0220] 3.11 Live Signal Processing and Lighting Applications

[0221] In artistic performance, composition, and recording applications, control of large numbers of parameters requiring simultaneous interactive adjustment is common. Conventional recording, mixing, video, and light control consoles typically have large numbers of controls with carefully designed spatial layouts to facilitate the rapid and precise adjustment of multiple parameters via knobs, sliders, push-buttons, toggle switches, etc. The introduction of computer GUIs has added considerable value and new capabilities, including “soft” reconfigurable consoles and functional assignments, but in the bargain, typically encumber users—accustomed to rapid and precise operation of multiple parameters—with a 2-parameter mouse/trackball/touchpad having the overhead of iterative context-switching operations depicted in FIGS. 8 and 9a-9b. As in the case of 3D object positioning and orientation, the division among high-overhead operations, for example moving among steps 901, 902, 903, can be functionally disruptive as well as slow and inefficient. The ability to interactively freely adjust larger collections of parameters simultaneously is thus also of extremely high value.

[0222] 3.12 Real-Time Machine Control and Plant Operations

[0223] Similarly, real-time machine control and plant (manufacturing, chemical, energy, etc.) operations also traditionally involve controlling a significant number of parameters requiring simultaneous interactive adjustment. Conventional real-time machine control and plant operation consoles typically have large numbers of controls with carefully designed spatial layouts to facilitate the rapid and precise adjustment of multiple parameters via knobs, sliders, push-buttons, toggle switches, etc. The introduction of computer GUIs can add considerable value and new capabilities, including “soft” reconfigurable consoles and functional assignments, but in the bargain typically significantly encumber users—accustomed to rapid and precise operation of multiple parameters—with a 2-parameter mouse/trackball/touchpad having the overhead of iterative context-switching operations depicted in FIGS. 8 and 9a-9b. As in the case of 3D object positioning/orientation and artistic applications described earlier, the division among high-overhead operations, for example moving among steps 901, 902, 903, can be functionally disruptive as well as slow and inefficient. The

ability to interactively freely adjust larger collections of parameters simultaneously is thus also of extremely high value.

[0224] A very few examples of this category of application where the invention may be useful include many forms of robotics control, computer-control manufacturing tools, industrial optical and electron microscopy, camera control (pan, tilt, zoom, focus, and/or iris), plant process elements (heaters, pumps, valves, stirrers, aerators, actuators, activators, etc.), and a wide range of other related and divergent possibilities apparent to those skilled in the art.

4. Concluding Remarks

[0225] The present invention at its core provides for a wide range of systems and methods for realizing and applying user interfaces providing, in many cases, at least four widely variable simultaneously interactively adjustable parameters. In so doing, the invention more broadly encompasses novel user interface structures, metaphors, and applications readily suggested and enabled by the core of the invention but which may be indeed realized in ways not involving the core of the invention.

[0226] While the invention has been described in detail with reference to disclosed embodiments, various modifications within the scope of the invention will be apparent to those of ordinary skill in this technological field. It is to be appreciated that features described with respect to one embodiment typically may be applied to other embodiments. Therefore, the invention properly is to be construed with reference to the claims.

I claim:

1. A computer interface device comprising:
 - a housing;
 - a first sensor for detecting a position change of the computer interface device on a surface, wherein the first sensor provides a first pair of parameters to indicate the position of the housing on the surface;
 - a touch pad configured with the housing, wherein the touch pad is configured to detect gestures and provides gesture signals responsive to the gestures;
 - a wireless link to transmit the first pair of parameters and the signals to a computing device,
 - wherein a cursor displayed on a screen of the computing device is controlled by the first pair of parameters, and wherein another displayed attribute of the computing device is controlled by the gesture signals.
2. A computer interface device comprising:
 - a housing;
 - a first sensor for detecting a position change of the computer interface device on a surface, wherein the first sensor positioning signals indicate the position change of the housing on the surface;
 - a touch pad configured with the housing, wherein the touch pad is configured to detect multiple points of contact of a plurality of contacting fingers and provides plurality touch signals responsive to the plurality of contacting fingers;
 - a wireless link to transmit the first pair of parameters and the signals to a computing device, and
 - wherein a cursor displayed on a screen of the computing device is controlled by the first pair of parameters, and wherein another displayed attribute of the computing device is controlled by the gesture signals.
